

This method has the advantage of being fast but it cannot be used where the pile is installed in strata with significant creep properties because load may be shed from the sides to the base without changes in the applied load (O'Neill and Hawkins, 1982).

Incremental Equilibrium Test (IE)

This test is a modification of the SML test and takes only about one-third of the SML test duration. Although the test is faster, the IE test was reported to provide similar correlations to the SML test (Fellenius, 1975). The IE test is conducted by applying increments of 15% to 25% of the design load and maintaining that load for about 10 minutes. The load then is allowed to drop (with the increase in settlement) until it becomes constant. At this point, equilibrium between the load and displacement is reached and the next increment is applied.

Constant-Time Interval Test (CTI)

Loading using this method is the same as that for the SML procedure. However, each load is maintained for exactly one hour. This procedure has a typical duration of about 10 hours.

Cyclic Test (CYC)

The cyclic test is conducted by a series of loading and unloading to the maximum test load. The rate of loading can be similar to that of the SML or CTI procedures. This test can be used where there is a need to determine the load at which creep displacements exceed certain limits. This procedure is time-consuming and is not typically used for routine load testing.

Controlled-Strain Methods

The controlled-strain methods are divided into two categories:

Constant-Rate Penetration Test (CRP)

In this test, the pile is made to penetrate the soil at a pre-determined constant rate, while the load applied is measured continuously. Average rates are 0.03 in/min for cohesive soils and 0.06 in/min for granular soils. The test can be performed in less than one hour, but it requires special equipment and trained personnel.

Constant Settlement Increment Test (CSI)

In this procedure, the load increments are determined from the load necessary to produce uniform increments of settlement of the pile head. Typical settlements are of the magnitude of 1% of the pile diameter. The load increment is varied in order to maintain the settlement magnitude.
