Abstract — Light Detection and Ranging (LIDAR) have recently become the technologies of choice in mass production of Digital Elevation Models (DEMs), Digital Terrain Models (DTMs), and Triangulated Irregular Networks (TINs), referred to generically hereafter as DEMs. This paper presents lessons learned from LIDAR projects to date in various states. It addresses opportunities presented by LIDAR for generating DEMs as articulated by various user groups in the National Height Modernization Study. Finally, it summarizes actions required by the remote sensing community to establish LIDAR as standard tools, with established standards, for generating digital elevation data for the new millennium.

* INTRODUCTION

LIDAR (Light Detection and Ranging) is an optical remote sensing technology that measures properties of scattered light to find range and/or other information of a distant target. The prevalent method to determine distance to an object or surface is to use [laser](#) pulses. Like the similar radar technology, which uses radio waves, the range to an object is determined by measuring the time delay between transmission of a pulse and detection of the reflected signal.

LIDAR technology has application geometries, [archaeology](#), [geography](#), [geology](#), [geomorphology](#), seismology, [remote sensing](#) and [atmospheric physics](#). [1] Applications of LIDAR include ALSM (Airborne Laser Swath Mapping), laser altimetry or [LIDAR Contour Mapping](#). The acronym LADAR (Laser Detection and Ranging) is often used in military contexts. The term laser radar is also in use but is misleading because it uses laser light and not the radiowaves that are the basis of conventional radar.

* GENERAL DESCRIPTION

The primary difference between LIDAR and RADAR is LIDAR uses much shorter [wavelengths](#) of the [electromagnetic spectrum](#), typically in the ultraviolet, visible, or [near infrared](#) range. In general it is possible to image a feature or object only about the same size as the wavelength, or larger. Thus LIDAR is highly sensitive to [aerosols](#) and [cloud](#) particles and has many applications in atmospheric research and meteorology.

An object needs to produce a [dielectric discontinuity](#) to reflect the transmitted wave. At radar ([microwave](#) or [radio](#)) frequencies, a [metallic](#) object produces a significant reflection. However non-metallic objects, such as rain and rocks produce weaker reflections and some materials may produce no detectable reflection at all, meaning some objects or features are effectively invisible at radar frequencies. This is especially true for very small objects (such as single [molecules](#) and [aerosols](#)).

Lasers provide one solution to these problems. The beam densities and coherency are excellent. Moreover the wavelengths are much smaller than can be achieved with radio systems, and range from about 10 [micrometers](#) to the UV (ca. 250 [nm](#)). At such wavelengths, the waves are "reflected" very well from small objects. This type of reflection is called [backscattering](#). Different types of scattering are used for different LIDAR applications, most common are [Rayleigh scattering](#), [Mie scattering](#) and [Raman scattering](#) as well as [fluorescence](#). Based on different kinds of backscattering, the LIDAR can be accordingly called Rayleigh LIDAR, Mie LIDAR, Raman LIDAR and Na/Fe/K Fluorescence LIDAR and so on. The wavelengths are ideal for making measurements of smoke and other airborne particles (aerosols), clouds, and air molecules.

A laser typically has a very narrow beam which allows the mapping of physical features with very high [resolution](#) compared with radar. In addition, many chemical compounds interact more strongly at visible wavelengths than at microwaves, resulting in a stronger image of these materials. Suitable combinations of lasers
