Section 1: 19%	Troubleshoot basic virtual server connectivity issues
Objective 1.01	Given a connectivity troubleshooting situation, consider the packet and virtual server processing order.

- Explain how a packet is processed once it arrives at a device (connection table, packet filters, etc.)
 - o Existing connection in connection table
 - o Packet filter rule
 - o Virtual server
 - <address>:<port>
 - <address>:*
 - <netmask>:<port>
 - <netmask>:*
 - *:<port>
 - *
 - o SNAT
 - o NAT
 - o Self-IP
 - o Drop
- Explain how a virtual server processes a request (most specific to least specific)
 - o When determining the order of precedence applied to new inbound connections, the BIG-IP uses an algorithm which places a higher precedence on the address netmask and a lesser emphasis on the port. BIG-IP sets virtual server precedence according to the following criteria:
 - The first precedent of the algorithm chooses the virtual server that has the longest subnet match for the incoming connection.
 - If the number of bits in the subnet mask match, the algorithm then chooses the virtual server that has a port match.
 - If no port match is found, the algorithm uses the wildcard server, if a wildcard virtual server is defined.
 - A wildcard address has a netmask length of zero, thus it has a lower precedence than any matching virtual server with a defined address.
