

Comparing timber shear connection design using EC 5 and BS 5268

Mark Clegg won the Michael Home Prize* 2008 for outstanding project work. Here he describes his research

This technical note reports on the current design methods adopted by the British Standard for several types of timber shear connections, and makes a comparison with the methods described in Eurocode 5. Calculations and verifying tests were conducted to determine which code most accurately predicted the load capacity of the connections.

Timber connections are a means of transferring loads from one member to another and ensuring stability of the overall structure. Early examples of timber connections consisted of simple wooden pegs and lap type joints, which were in keeping with the simple construction that was present in those times. As time has passed and structures have become more complex, so have the means by which members are connected. Today, a large variety of fasteners are available, enabling strong connections to be achieved in a speedy and economical manner.

There are several different ways in which timber can be connected to steel, the differing forms which are being applied. This technical note deals with single and double shear type connections with dowel type fasteners.

Previous research

The current method of connection design was established by H. W. Johansen in 1948 when he developed his 'yield model'. This paper he published clarified that the strength of a simple connection is a function of the fastener's tensile strength, the timber's crushing strength, and the amount of load required to pull it in between out of the timber. Johansen developed formulae leading to three possible failure modes for single shear connections, and four possible modes for double shear connections.

Design codes and methods

Connection design in the UK, is currently based on BS 5268:2002 Structural Use of Timber. It is expected that in 2012, this will be replaced by the European Standard, EN 1995-1-1:2004, Eurocode 5: Design of Timber Structures¹ along with the relevant UK National Application Document.

Both codes of practice are based on the research conducted by Johansen, although additional failure modes have been identified, and the formulae have been adapted to account for variable timber sizes and embedding strengths of the timber.

When comparing the formulae from both codes, it was seen that in general only minor changes have been implemented, although there is a clear difference to equations 4 through 7 for single shear failure and 5 to 8 for double shear failure. This is the reduction of $F_{t,k}/k$ in the Eurocode, which represents an increase in strength due to what is described as the 'characteristic axial withdrawal capacity of the fastener', which was realised by Johansen in his research but not used in BS 5268.

The characteristic axial withdrawal capacity allowed for by Eurocode 5 occurs when the fastener has rotated within the timber and a withdrawal force is introduced into the fastener by means of friction between the fastener and the timber. The amount of load resisted by this frictional effect varies depending on factors such as the timber resistance to other fasteners, the thickness and density of the timber, and the size of the fastener itself.

The method adopted for the comparison is summarised in Fig 1.

Determining the theoretical connection capacities

Initially numerous calculations were conducted to determine the load capacity of a vast variety of connection types. It was fundamental that the two codes were compared by a fair means. The British Standard is based upon characteristic stress design, so a material safety factor has already been applied to the ultimate failure stresses, thus the loads applied are true unfactored loads. Eurocode 5 adopts the alternative approach of limit state philosophy, whereby characteristic loads (50th percentile) are increased by a partial safety factor and the characteristic failure stresses (50th percentile) are reduced by a partial safety factor.

To illustrate this problem the ultimate stresses of the timber were based on the values provided by BS EN 338:2003 Structural Timber – 'Strength classes' which gives unmodified design stresses.

When considering timber it is apparent that many variations can
