Optimization-Based Models for Measuring and Hedging Risk in Fixed Income Markets Johan Hagenbjörk, 2019-12-09 The global fixed income market is an enormous financial market whose value by far exceeds that of the public stock markets The interbank market consists of interest rate derivatives whose primary purpose is to manage interest rate risk The credit market primarily consists of the bond market which links investors to companies institutions and governments with borrowing needs This dissertation takes an optimization perspective upon modeling both these areas of the fixed income market Legislators on the national markets require financial actors to value their financial assets in accordance with market prices Thus prices of many assets which are not publicly traded must be determined mathematically The financial quantities needed for pricing are not directly observable but must be measured through solving inverse optimization problems These measurements are based on the available market prices which are observed with various degrees of measurement noise For the interbank market the relevant financial quantities consist of term structures of interest rates which are curves displaying the market rates for different maturities For the bond market credit risk is an additional factor that can be modeled through default intensity curves and term structures of recovery rates in case of default By formulating suitable optimization models the different

underlying financial quantities can be measured in accordance with observable market prices while conditions for economic realism are imposed. Measuring and managing risk is closely connected to the measurement of the underlying financial quantities. Through a data driven method we can show that six systematic risk factors can be used to explain almost all variance in the interest rate curves. By modeling the dynamics of these six risk factors possible outcomes can be simulated in the form of term structure scenarios. For short term simulation horizons this results in a representation of the portfolio value distribution that is consistent with the realized outcomes from historically observed term structures. This enables more accurate measurements of interest rate risk where our proposed method exhibits both lower risk and lower pricing errors compared to traditional models. We propose a method for decomposing changes in portfolio values for an arbitrary portfolio into the risk factors that affect the value of each instrument. By demonstrating the method for the six systematic risk factors identified for the interbank market we show that almost all changes in portfolio value and portfolio variance can be attributed to these risk factors. Additional risk factors and approximation errors are gathered into two terms which can be studied to ensure the quality of the performance attribution and possibly improve it. To eliminate undesired risk within trading books banks use hedging. Traditional methods do not take transaction costs into account. We therefore propose a method for managing the risks in the interbank market through a stochastic optimization model that considers transaction costs. This method is based on a scenario approximation of the optimization problem where the six systematic risk factors are simulated and the portfolio variance is weighted against the transaction costs. This results in a method that is preferred over the traditional methods for all risk averse investors. For the credit market we use data from the bond market in combination with the interbank market to make accurate measurements of the financial quantities. We address the notoriously difficult problem of separating default risk from recovery risk. In addition to the previous identified six systematic risk factors for risk free interests we identify four risk factors that explain almost all variance in default intensities while a single risk factor seems sufficient to model the recovery risk. Overall this is a higher number of risk factors than is usually found in the literature. Through a simple model we can measure the variance in bond prices in terms of these systematic risk factors and through performance attribution we relate these values to the empirically realized variances from the quoted bond prices.
