## DNA and variation

Single gene is passed on through time → part of revolutionary process  
DNA replicates in individuals – evolution happens in populations

Selection pressure: *a force that causes a particular organism to evolve in a certain direction*  
➤ Favourable mutation may increase chances of survival

### Sources of genetic variation

1. Genetic mutation - nucleotide-pair substitution
  - Silent (synonymous): *does not affect amino acid* i.e. third position in codon
  - Missense: *altering phenotype*
  - Non sense: *protein no longer created*
2. Genetic mutation – nucleotide-pair insertion or deletion
  - Frameshift causing immediate/extensive non sense
  - Insertion of entirely new amino acid
3. Random mutations create allelic variation
4. Recombination and independent assortment in sexually reproducing organs

Genetic variation affects individual's fitness – can be deleterious, neutral or advantageous  
➤ Germ-line (meiosis) mutations matter  
➤ Somatic (mitosis) mutations matter to individual but are not heritable (i.e. cancer)

## Hardy-Weinberg principle (1908)

*Frequency of alleles and genotypes in a population will remain constant from generation to generation providing:*

- Only Mendelian segregation applies
- Recombination of alleles is occurring

Gene pool not evolving assumes:

- No mutations
- No gene flow
- No selection
- Random mating
- Large population

$$\text{Equilibrium} = p^2 + 2pq + q^2$$

$$\text{Genotype frequency} = \frac{\text{no. species with particular genotype}}{\text{total no. species}}$$

$$\text{Allele frequency} = \frac{\text{no. of particular allele (i.e. 2 x homozygous + 1 x heterozygous count)}}{\text{total no. alleles}}$$

## Evolutionary processes

Evolution: *a change in the frequency of alleles over space and time in the gene pool of a reproducing population*
