The Mobile Agent Rendezvous Problem in the Ring Evangelos Kranakis, Danny Krizanc, Euripides Marcou, 2022-05-31

Mobile agent computing is being used in fields as diverse as artificial intelligence computational economics and robotics Agents ability to adapt dynamically and execute asynchronously and autonomously brings potential advantages in terms of fault tolerance flexibility and simplicity This monograph focuses on studying mobile agents as modelled in distributed systems research and in particular within the framework of research performed in the distributed algorithms community It studies the fundamental question of how to achieve rendezvous the gathering of two or more agents at the same node of a network Like leader election such an operation is a useful subroutine in more general computations that may require the agents to synchronize share information divide up chores etc The work provides an introduction to the algorithmic issues raised by the rendezvous problem in the distributed computing setting For the most part our investigation concentrates on the simplest case of two agents attempting to rendezvous on a ring network Other situations including multiple agents faulty nodes and other topologies are also examined An extensive bibliography provides many pointers to related work not covered in the text The presentation has a distinctly algorithmic rigorous distributed computing flavor and most results should be easily accessible to advanced undergraduate and graduate students in computer science and mathematics departments

Schwarzmann, 2022-05-31 Providing a shared memory abstraction in distributed systems is a powerful tool that can simplify the design and implementation of software systems for networked platforms This enables the system designers to work with abstract readable and writable objects without the need to deal with the complexity and dynamism of the underlying platform The key property of shared memory implementations is the consistency guarantee that it provides under concurrent access to the shared objects The most intuitive memory consistency model is atomicity because of its equivalence with a memory system where accesses occur serially one at a time Emulations of shared atomic memory in distributed systems is an active area of research and development The problem proves to be challenging and especially so in distributed message passing settings with unreliable components as is often the case in networked systems We present several approaches to implementing shared memory services with the help of replication on top of message passing distributed platforms subject to a variety of perturbations in the computing medium **Network Topology and Fault-Tolerant Consensus** Dimitris Sakavalas, Lewis Tseng, 2022-05-31 As the structure of contemporary communication networks grows more complex practical networked distributed systems become prone to component failures Fault tolerant consensus in message passing systems

allows participants in the system to agree on a common value despite the malfunction or misbehavior of some components. It is a task of fundamental importance for distributed computing due to its numerous applications. We summarize studies on the topological conditions that determine the feasibility of consensus, mainly focusing on directed networks and the case of restricted topology knowledge at each participant. Recently, significant efforts have been devoted to fully characterize the underlying communication networks in which variations of fault-tolerant consensus can be achieved. Although the deduction of analogous topological conditions for undirected networks of known topology had shortly followed the introduction of the problem, their extension to the directed network case has been proven a highly non-trivial task. Moreover, global knowledge restrictions inherent in modern large-scale networks require more elaborate arguments concerning the locality of distributed computations. In this work, we present the techniques and ideas used to resolve these issues. Recent studies indicate a number of parameters that affect the topological conditions under which consensus can be achieved, namely the fault model, the degree of system synchrony (synchronous vs asynchronous), the type of agreement (exact vs approximate), the level of topology knowledge, and the algorithm class used (general vs iterative). We outline the feasibility and impossibility results for various combinations of the above parameters, extensively illustrating the relation between network topology and consensus.

Impossibility Results for Distributed Computing Hagit Attiya, Faith Ellen, 2022-06-01 To understand the power of distributed systems, it is necessary to understand their inherent limitations: what problems cannot be solved in particular systems or without sufficient resources such as time or space. This book presents key techniques for proving such impossibility results and applies them to a variety of different problems in a variety of different system models. Insights gained from these results are highlighted, aspects of a problem that make it difficult are isolated, features of an architecture that make it inadequate for solving certain problems efficiently are identified, and different system models are compared.

Introduction to Distributed Self-Stabilizing Algorithms Karine Altisen, Stéphane Devismes, Swan Dubois, Franck Petit, 2022-05-31 This book aims at being a comprehensive and pedagogical introduction to the concept of self-stabilization introduced by Edsger Wybe Dijkstra in 1973. Self-stabilization characterizes the ability of a distributed algorithm to converge within finite time to a configuration from which its behavior is correct, i.e. satisfies a given specification regardless the arbitrary initial configuration of the system. This arbitrary initial configuration may be the result of the occurrence of a finite number of transient faults. Hence, self-stabilization is actually considered as a versatile non-masking fault-tolerance approach since it recovers from the effect of any finite number of such faults in a unified manner. Another major interest of such an automatic recovery method comes from the difficulty of resetting malfunctioning devices in a large-scale and so geographically spread distributed system. The Internet Pair-to-Pair networks and Delay-Tolerant Networks are examples of such distributed systems. Furthermore, self-stabilization is usually recognized as a lightweight property to achieve fault tolerance as compared to other classical fault-tolerance approaches. Indeed, the overhead both in terms of time and space of

state of the art self stabilizing algorithms is commonly small This makes self stabilization very attractive for distributed systems equipped of processes with low computational and memory capabilities such as wireless sensor networks After more than 40 years of existence self stabilization is now sufficiently established as an important field of research in theoretical distributed computing to justify its teaching in advanced research oriented graduate courses This book is an initiation course which consists of the formal definition of self stabilization and its related concepts followed by a deep review and study of classical simple algorithms commonly used proof schemes and design patterns as well as premium results issued from the self stabilizing community As often happens in the self stabilizing area in this book we focus on the proof of correctness and the analytical complexity of the studied distributed self stabilizing algorithms Finally we underline that most of the algorithms studied in this book are actually dedicated to the high level atomic state model which is the most commonly used computational model in the self stabilizing area However in the last chapter we present general techniques to achieve self stabilization in the low level message passing model as well as example algorithms

Distributed Computing Pearls Gadi Taubenfeld, 2022-05-31 Computers and computer networks are one of the most incredible inventions of the 20th century having an ever expanding role in our daily lives by enabling complex human activities in areas such as entertainment education and commerce One of the most challenging problems in computer science for the 21st century is to improve the design of distributed systems where computing devices have to work together as a team to achieve common goals In this book I have tried to gently introduce the general reader to some of the most fundamental issues and classical results of computer science underlying the design of algorithms for distributed systems so that the reader can get a feel of the nature of this exciting and fascinating field called distributed computing The book will appeal to the educated layperson and requires no computer related background I strongly suspect that also most computer knowledgeable readers will be able to learn something new

Distributed Graph Coloring Leonid Barenboim, Michael Elkin, 2022-06-01 The focus of this monograph is on symmetry breaking problems in the message passing model of

distributed computing In this model a communication network is represented by a n vertex graph $G(V, E)$ whose vertices host autonomous processors The processors communicate over the edges of G in discrete rounds The goal is to devise algorithms that use as few rounds as possible A typical symmetry breaking problem is the problem of graph coloring Denote by the maximum degree of G While coloring G with 1 colors is trivial in the centralized setting the problem becomes much more challenging in the distributed one One can also compromise on the number of colors if this allows for more efficient algorithms Other typical symmetry breaking problems are the problems of computing a maximal independent set MIS and a maximal matching MM The study of these problems dates back to the very early days of distributed computing The founding fathers of distributed computing laid firm foundations for the area of distributed symmetry breaking already in the eighties In particular they showed that all these problems can be solved in randomized logarithmic time Also Linial showed that an $O(2)$ coloring can be solved very efficiently deterministically However fundamental questions were left open for decades In particular it is not known if the MIS or the 1 coloring can be solved in deterministic polylogarithmic time Moreover until recently it was not known if in deterministic polylogarithmic time one can color a graph with significantly fewer than 2 colors Additionally it was open and still open to some extent if one can have sublogarithmic randomized algorithms for the symmetry breaking problems Recently significant progress was achieved in the study of these questions More efficient deterministic and randomized 1 coloring algorithms were achieved Deterministic $O(1)$ coloring algorithms with polylogarithmic running time were devised Improved and often sublogarithmic time randomized algorithms were devised Drastically improved lower bounds were given Wide families of graphs in which these problems are solvable much faster than on general graphs were identified The objective of our monograph is to cover most of these developments and as a result to provide a treatise on theoretical foundations of distributed symmetry breaking in the message passing model We hope that our monograph will stimulate further progress in this exciting area

Message-passing Systems Michel Raynal, 2022-06-01 Understanding distributed computing is not an easy task This is due to the many facets of uncertainty one has to cope with and master in order to produce correct distributed software A previous book Communication and Agreement Abstraction for Fault tolerant Asynchronous Distributed Systems published by Morgan Claypool 2010 was devoted to the problems created by crash failures in asynchronous message passing systems The present book focuses on the way to cope with the uncertainty created by process failures crash omission failures and Byzantine behavior in synchronous message passing systems i.e systems whose progress is governed by the passage of time To that end the book considers fundamental problems that distributed synchronous processes have to solve These fundamental problems concern agreement among processes if processes are unable to agree in one way or another in presence of failures no non trivial problem can be solved They are consensus interactive consistency k set agreement and non blocking atomic commit Being able to solve these basic problems efficiently with provable guarantees allows applications
