Higher-Level Hardware Synthesis Richard Sharp, 2004-03-12 In the mid 1960s when a single chip contained an average of 50 transistors Gordon Moore observed that integrated circuits were doubling in complexity every year In an influential article published by Electronics Magazine in 1965 Moore predicted that this trend would continue for the next 10 years Despite being criticized for its unrealistic optimism Moore's prediction has remained valid for far longer than even he imagined today chips built using state the art techniques typically contain several million transistors The advances in fabrication technology that have supported Moore's law for four decades have fuelled the computer revolution However this exponential increase in transistor density poses new design challenges to engineers and computer scientists alike New techniques for managing complexity must be developed if circuits are to take full advantage of the vast numbers of transistors available In this monograph we investigate both i the design of high level languages for hardware description and ii techniques involved in translating these hi level languages to silicon We propose SAFL a rst order functional language designed speci cally for behavioral hardware description and describe the implementation of its associated silicon compiler We show that the high level properties of SAFL allow one to exploit program analyses and optimizations that are not employed in existing synthesis systems Furthermore since SAFL fully abstracts the low level details of the implementation technology we show how it can be compiled to a range of different design styles including fully synchronous design and globally asynchronous locally synchronous GALS circuits
