AP Biology Exam

Section 1: Photosynthesis

Introduction

- Photosynthesis** is the process by which plants and other organisms use light energy to produce glucose and oxygen from carbon dioxide and water.
- Chloroplasts** are the organelles in plant cells where photosynthesis takes place. They contain chlorophyll, the green pigment that captures light energy.
- Light-dependent reactions** are the first stage of photosynthesis, where light energy is used to produce ATP and NADPH. These reactions occur in the thylakoid membranes of the chloroplast.
- Calvin cycle** is the second stage of photosynthesis, where carbon dioxide is fixed into glucose. This cycle occurs in the stroma of the chloroplast.
- Photosynthesis equation**: $6\text{CO}_2 + 6\text{H}_2\text{O} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$
- Factors affecting photosynthesis**: Light intensity, carbon dioxide concentration, and temperature all affect the rate of photosynthesis.
- Limiting factor** is a factor that restricts the rate of a process. In photosynthesis, it could be light intensity, carbon dioxide concentration, or temperature.
- Photorespiration** is a process that occurs when the enzyme RuBisCO reacts oxygen with ribulose biphosphate (RuBP) instead of carbon dioxide, leading to a loss of energy and a decrease in photosynthetic efficiency.
- C4 pathway** is a type of photosynthesis that occurs in some plants, where carbon dioxide is first fixed into a four-carbon compound before entering the Calvin cycle.
- C3 pathway** is the most common type of photosynthesis, where carbon dioxide is directly fixed into a three-carbon compound.
- Photoautotrophs** are organisms that can produce their own food using light energy and inorganic carbon sources.

Significance

Photosynthesis

- How does photosynthesis occur in plants? (10 points)
 - Light energy is absorbed by chlorophyll in the thylakoid membranes of the chloroplast.
 - This energy is used to split water molecules into oxygen and protons.
 - The electrons from water are used to reduce NADP+ to NADPH.
 - The protons are used to create a proton gradient across the thylakoid membrane, which drives the synthesis of ATP.
 - The oxygen is released as a byproduct.
- What are the two main stages of photosynthesis? (10 points)
 - Light-dependent reactions: These reactions occur in the thylakoid membranes and produce ATP and NADPH.
 - Calvin cycle: This cycle occurs in the stroma and uses ATP and NADPH to fix carbon dioxide into glucose.
- How does the structure of the chloroplast relate to its function? (10 points)
 - The thylakoid membranes are stacked into grana, which increases the surface area for light-dependent reactions.
 - The stroma is the fluid-filled space surrounding the thylakoids, where the Calvin cycle takes place.
 - The chloroplast envelope is a double membrane that separates the chloroplast from the rest of the cell.
 - The presence of a large central vacuole in plant cells helps maintain turgor pressure, which is essential for photosynthesis.
- What factors affect the rate of photosynthesis? (10 points)
 - Light intensity: The rate of photosynthesis increases with light intensity up to a point, after which it plateaus.
 - Carbon dioxide concentration: The rate of photosynthesis increases with carbon dioxide concentration up to a point, after which it plateaus.
 - Temperature: The rate of photosynthesis increases with temperature up to an optimal point, after which it decreases.
 - Water availability: A lack of water can lead to stomatal closure, which reduces the intake of carbon dioxide and thus the rate of photosynthesis.
