

Modeling Seafloor Spreading

Your Challenge

1. Create a model of seafloor spreading and subduction zones using the steps below or your own method.
2. Use it and the information below to help you answer the questions at the end of the handout.

Background

The creation of new seafloor at **mid-ocean ridges** (spreading centers) is one of many cycles that cause the Earth to experience constant change. They occur where two **tectonic plates** of the Earth's crust are moving away from each other. For this reason, they are also known as **divergent plate boundaries**, and they result in deep cracks in the crust.

Seafloor is constantly destroyed in **subduction zones** (also known as **convergent**—meaning coming together—**plate boundaries**). New seafloor is made from rising **magma** (liquid rock), that cools to form solid **igneous** rocks.

The Earth has a **magnetic field**, which is thought to arise from the movement of liquid iron in the outer core of the planet as it rotates. The field behaves as if a magnet were located near the center of the Earth. Igneous rocks contain magnetic minerals, which aligned with the Earth's magnetic field when they were in magma. The magnetic minerals are like compasses in the magma, swiveling to point north, but they can no longer do so when the rock becomes solid. In this way, the geologic memory of the direction of magnetic north is forever locked in that rock.
