

## GATEWAY<sup>®</sup> AND TOPO CLONING

### Introduction to Gateway Cloning

---

Gateway Cloning Technology is Invitrogen's universal cloning system that provides a rapid and highly efficient route to protein expression, functional analysis and cloning/subcloning of DNA segments. This system is based on the well-characterized bacteriophage lambda-based site-specific recombination system ( $\text{attL} \times \text{attR} \leftrightarrow \text{attB} \times \text{attP}$ ). In overview, Gateway is a 2-step cloning process; in the first step a sequence of interest is inserted into an Entry Clone. The second step transfers the sequence into a variety of  $\text{attB}$ -containing Expression Clones that can be propagated and expressed in a range of host cells for a given experiment.

TOPO Technology is a fast, efficient way to clone. The key to TOPO Cloning is the enzyme DNA topoisomerase I, whose biological role is to cleave and rejoin DNA during replication. To harness this activity, vectors are linearized and each end is conjugated with topoisomerase on the 3' phosphate. This enables fast ligation of DNA sequences with compatible ends. After 5 minutes at room temperature, enzyme is released, the ligation is complete and the recombinant molecule is ready for transformation into *E. coli*. Many Invitrogen expression vectors are adapted for one-step TOPO Cloning of PCR products in both directional and non-directional formats. Other vectors contain  $\text{att}$  recombination sequences exterior to the TOPO cloning sites so that cloned inserts are ready for entry into the Gateway system.

Vector NTI Advance 10 offers an interlocking set of computational tools for planning Gateway or TOPO cloning experiments from beginning to end. These allow you to simulate recombinant strategy, as well as to validate design of your reagents before proceeding to primer ordering, bench-top operations, etc. Steps necessary to identify and screen transformants, expedite purification, fuse an insert with vector tags, etc. can be identified and modifications made before

*Autophagy in plants and algae* Diane C Bassham, Jose L Crespo, 2015-05-15 Autophagy also known as macroautophagy is an evolutionarily conserved process by which cytoplasmic components are nonselectively enclosed within a double membrane vesicle known as the autophagosome and delivered to the vacuole for degradation of toxic components and recycling of needed nutrients This catabolic process is required for the adequate adaptation and response of the cell and correspondingly the whole organism to different types of stress including nutrient starvation or oxidative damage Autophagy has been extensively investigated in yeasts and mammals but the identification of autophagy related ATG genes in plant and algal genomes together with the characterization of autophagy deficient mutants in plants have revealed that this process is structurally and functionally conserved in photosynthetic eukaryotes Recent studies have demonstrated that autophagy is active at a basal level under normal growth in plants and is upregulated during senescence and in response to nutrient limitation oxidative stress salt and drought conditions and pathogen attack Autophagy was initially considered as a non selective pathway but numerous observations mainly obtained in yeasts revealed that autophagy can also selectively eliminate specific proteins protein complexes and organelles Interestingly several types of selective autophagy appear to be also conserved in plants and the degradation of protein aggregates through specific adaptors or the delivery of chloroplast material to the vacuole via autophagy has been reported This research topic aims to gather recent progress on different aspects of autophagy in plants and algae We welcome all types of articles including original research methods opinions and reviews that provide new insights about the autophagy process and its regulation
