Water Chemistry and Pretreatment: Silica Scale Prevention

Silica Scale Prevention

Dissolved silica (SiO_2) is naturally present in most feed waters in the range of 1–100 mg/L. The prevailing forms of silica are meta silicic acids as $(\text{H}_2\text{SiO}_3)_n$ with low n numbers. Since silicic acid is a weak acid, it is mostly in the undissociated form at or below a neutral pH. Supersaturated silicic acid can further polymerize to form insoluble colloidal silica or silica gel, which can cause membrane scaling. The maximum allowable SiO_2 concentration in the concentrate stream is based on the solubility of SiO_2 .

The scaling potential for the concentrate stream will be quite different from that of the feed solution because of the increase in the concentration of SiO_2 and the change in pH. It can be calculated from the feed water analysis and the RO operating parameters.

As the pH exceeds neutral, silicic acid dissociates into the silicate anion (SiO_3^{2-}). This can react with calcium, magnesium, iron, manganese or aluminum to form insoluble silicates.

It was indicated that aluminum is the most powerful precipitant of silicic acid /12/, and the occurrence of silica scaling is mostly correlated with the occurrence of aluminum or iron /13/. It has been reported that, when Al^{3+} and Fe^{3+} coexist in the pretreated feed water, silica is precipitated even below its saturation /14, 15/. Both Al^{3+} and Fe^{3+} , therefore, must be less than 0.05 mg/L in the feed water, even if the silica level is below saturation. Since Al^{3+} and Fe^{3+} salts are used for coagulation in municipal and other industrial water processing, frequent and accurate measurements of these ions are needed even though the feed water itself does not contain high levels of aluminum and iron ions. Fouling with metal silicates may occur from a chemical reaction and precipitation process (scaling), and also from colloidal fouling with submicron particles entering the membrane system. Feed water acidification and preventive acid cleanings are possible measures in cases of a metal silica scaling potential. If colloidal silica and silicates are present in the feed water, a flocculation/filtration process and/or a fine grade prefilter (1 μm or less) should be chosen.

The scaling potential of soluble silica (silicic acid) in the absence of trivalent metal cations can be calculated as follows. The calculation requires the following data for the feed solution (after acid addition, if acid is used for control of calcium carbonate):

- SiO_2 concentration
- Temperature
- pH
- Total alkalinity

Calculation /16/

1. The SiO_2 concentration in the concentrate stream is calculated from the SiO_2 concentration in the feed solution and the recovery of the reverse osmosis system:

$$\text{SiO}_{2,c} = \text{SiO}_{2,f} \left(\frac{1}{1-Y} \right)$$

where:

$\text{SiO}_{2,c}$ = silica concentration in concentrate as SiO_2 , mg/L

$\text{SiO}_{2,f}$ = silica concentration in feed as SiO_2 , mg/L

Y = recovery of the reverse osmosis system, expressed as a decimal

2. Calculate the pH of the concentrate stream from the pH of the feed stream using the procedure given in [Calcium Carbonate Scale Prevention \(Section 2.4.2\)](#).
