Abstract
 The purpose of this study was to investigate the effect of a 12-week training program on the physical and psychological health of elderly people. The study was conducted in a community center in Tehran, Iran. The participants were 30 elderly people (15 men and 15 women) aged 65 and above. They were divided into two groups: a control group and an experimental group. The experimental group participated in a 12-week training program consisting of aerobic exercises, strength training, and flexibility exercises. The control group did not participate in any training program. The physical health of the participants was measured using a series of tests, including a 6-minute walk test, a 30-second chair stand test, and a handgrip strength test. The psychological health of the participants was measured using a series of questionnaires, including the Geriatric Depression Scale (GDS), the Geriatric Anxiety Inventory (GAI), and the Geriatric Life Satisfaction Scale (GLSS). The results of the study showed that the experimental group had significantly better physical and psychological health than the control group after 12 weeks of training. The 6-minute walk test results showed that the experimental group had a significantly higher distance walked than the control group. The 30-second chair stand test results showed that the experimental group had a significantly higher number of stands than the control group. The handgrip strength test results showed that the experimental group had a significantly higher handgrip strength than the control group. The GDS results showed that the experimental group had a significantly lower score than the control group, indicating a lower level of depression. The GAI results showed that the experimental group had a significantly lower score than the control group, indicating a lower level of anxiety. The GLSS results showed that the experimental group had a significantly higher score than the control group, indicating a higher level of life satisfaction. The results of this study suggest that a 12-week training program can improve the physical and psychological health of elderly people.

These data suggest that the use of a single, large, open-ended question to assess the frequency of use of a specific behavior may be less reliable than the use of a series of questions that ask about the frequency of use of specific behaviors. The use of a series of questions may be more reliable because it allows the respondent to provide more detailed information about the frequency of use of a specific behavior.

Abstract The purpose of this study was to determine the effect of a 12-week, low-intensity, supervised walking program on the physical and psychological health of sedentary, middle-aged women. The study was a randomized, controlled trial. The intervention group (n = 20) participated in a 12-week walking program, while the control group (n = 20) remained sedentary. The walking program was designed to be low-intensity and supervised. The program was evaluated using a variety of physical and psychological measures. The results of the study showed that the walking program had a positive effect on the physical and psychological health of the women. The women in the walking program showed significant improvements in physical fitness, including increased aerobic capacity, muscle strength, and flexibility. They also showed significant improvements in psychological health, including reduced stress, anxiety, and depression. The results of the study suggest that a 12-week, low-intensity, supervised walking program can be an effective intervention for improving the physical and psychological health of sedentary, middle-aged women.
